

# IgG Food Sensitivity

## Clinical Information for Professionals

### IgG TYPE III DELAYED HYPERSENSITIVITY REACTIONS

Circulating IgG antibodies form immune complexes with allergen/antigen (Ag). This is considered a Type III delayed hypersensitivity reaction, and typically occurs over several hours to several days.

Formation of the complexes activates the complement pathway and releases inflammatory mediators.

The IgG-Ag immune complexes are usually cleared by macrophages but, in the presence of excess antigen, macrophages may saturate their capacity to remove immune complexes, causing the excess to be deposited in tissue. Deposition of IgG-Ag complexes causes inflammation and tissue damage, which may contribute to specific health issues.

There are four subclasses of IgG: IgG1, IgG2, IgG3 and IgG4. All subclasses activate the classical complement pathway except for IgG4. Our IgG test measures all four subclasses, and reports the result as total IgG.

### CLINICAL RELEVANCE

Although still controversial in mainstream medicine, IgG food sensitivity testing is starting to accumulate research in support of its clinical utility. For example, 125 patients, identified by an allergist as likely having food allergies, were given blood tests for IgG food reactions. All positive foods were removed for a 6 month period. The allergist considered the treatment a success when a minimum 75% improvement in symptoms occurred. Of the 80 patients who completed the full course, 71% were successfully treated. In particular, there were 11 patients who had positive allergy symptoms, but had negative IgE test results. These patients were all successfully treated by eliminating the IgG food allergens. The allergist concluded that blood tests for IgG reactions to food were clinically useful and much more palatable to patients than the traditional skin prick and oral challenge tests.

Although he acknowledged that the lack of blinding and randomization meant the results could be considered anecdotal, the allergist concluded that eliminating reactive foods was useful clinically.<sup>1</sup>

IgG testing for food is not considered diagnostic for food reactions because a direct cause-effect relationship has not been established. Elevated levels of IgG have not yet been proven to cause patient symptoms, however, more studies are emerging to show a correlation between elevated IgG reactions and a variety of conditions.

### IgG FOOD SENSITIVITY

IgG delayed onset reactions can contribute to a variety of health problems. abdominal pain, gas, and bloating.

# IgG Food Sensitivity

## IRRITABLE BOWEL SYNDROME

A double-blind 2004 British study randomized 150 patients to receive either a sham diet or true diet. The true diet group eliminated all IgG reactive foods, and the sham diet group excluded the same number of foods as showed up reactive, but not the actual reactive foods. The severity of IBS symptoms, non-IBS related symptoms, anxiety/depression and quality of life scores were obtained at the start and again after three months on either diet. At the end of the study, the true diet group had significantly reduced severity of IBS symptoms and overall symptoms compared to the sham diet group.<sup>2</sup>

## MIGRAINE

A 2004 study looked at the relationship between IgG food reactions and migraine attacks. In the study, 61 people were tested via IgG ELISA for 113 foods. About 90% of participants eliminated some or all of the reactive foods from their diet. At 1 month, 30% reported marked improvement, and at 2 months 40% reported benefit. Reintroduction of the reactive foods into the diet resulted in return of migraine for 60% of these patients. This study suggests that IgG reactions to food may play a role in the etiology and/or treatment of migraine attacks.<sup>3</sup>

A 2010 randomized, double-blind, crossover trial also showed a statistically significant drop in the number of headache days, and the number of headaches during the six week period when IgG reactive foods were eliminated from the diet.<sup>4</sup>

## WEIGHT GAIN / ATHEROSCLEROSIS

A paper published in 2008 reported that obese children have significantly higher IgG antibodies to food antigens than normal weight children. They also found that anti-food IgG antibody concentrations are strongly associated with low grade systemic inflammation and with increased intima media thickness of the common carotid arteries. The study concluded that: "These findings raise the possibility that anti-food IgG is pathogenically involved in the development of obesity and atherosclerosis."<sup>5</sup>

## ATOPY

Allergic individuals and those with atopy achieved 70% reduction of symptoms with elimination of IgG reactive foods.<sup>6</sup> In addition, atopic children (with or without eczema) were shown to have higher IgG levels to specific foods than non-atopic children. In children without eczema, higher levels of IgG were still significantly associated with atopy, with elevated IgG most prominently to egg white, orange and cow's milk.<sup>7</sup>

## RHEUMATOID ARTHRITIS

Some rheumatoid arthritis patients have shown improvement in symptoms when reactive foods were eliminated from the diet. It has been hypothesized that patients with occasional rheumatitis may experience delayed hypersensitivity food reactions.<sup>8</sup>

## ADHD

Although no studies directly correlate elevated IgG levels to specific foods with hyperactivity in children, a few studies have shown improvement in attentiveness and temperament when common food allergens (e.g. wheat, dairy, oranges) were eliminated.

# IgG Food Sensitivity

NON-IMMUNE MEDIATED REACTIONS			
Implicated Substance		Associated Foods	Nausea, Diarrhea, Gas, Bloating, And Abdominal Cramps
Enzymes	Lactase Deficiency	Lactose In Dairy Products	Nausea, diarrhea, gas, bloating, and abdominal cramps
	Alpha-Galactosidase Insufficiency	Cruciferous Vegetables, Legumes	Gas, bloating
Chemicals	Histamine	Fish, Sauerkraut, Cheese	Headaches, rashes, itching, diarrhea, vomiting and/or abdominal pain
	Methylxanthine	Cola, Coffee, Chocolate, Tea	Anxiety, panic disorders
	Tyramine	Cheese, Pickled Herring	Headache, palpitations, nausea, vomiting
	Tryptamine	Fermented Foods (Soy Sauce), Acacia Species (Incl. Beans)	Restlessness, agitation, gastrointestinal distress, muscle tension, may be hallucinogenic
Toxins	Aflatoxin	Peanuts, Cereal Grains	Chronic exposure: liver disease, increased risk of liver cancer
	Saxitoxin	Shellfish	Inhalation: numbness & tingling of lips, tongue, and fingertips, followed by numbness of the neck and extremities and motor incoordination. Other symptoms may include light-headedness, dizziness, weakness, confusion, memory loss, and headache
	Ergot	Cereal Grains	Numbness, tingling & burning in limbs, feeble pulse, restlessness, stupor, delirium
	Cyanogenic Glycosides	Cassava, Stone Fruits (E.g. Peach, Apricot)	Chronic exposure may lead to thyroid and neurological disorders

# IgG Food Sensitivity

The chart below highlights the clinical picture for the various phases of IgG food sensitivity reactions [Adapted from Dixon and Trevino. Food Allergy. 1997. Thieme Medical Publishing].<sup>9</sup>

CLINICAL PHASES OF IGG REACTIONS		
I	<b>Hidden Phase</b>	Small amounts of the reactive food are eaten. Antibody-allergen complexes form, but are removed by macrophages. Patient is asymptomatic.
II	<b>Symptomatic Phase</b>	Reactive food is eaten in large quantities and regularly. Large numbers of antibody-allergen complexes form and cannot be completely cleared by macrophages. Patient suffers chronic symptoms.
III	<b>Trial Avoidance Phase</b>	Patient removes reactive foods from diet. Levels of IgG antibodies to reactive foods remain high.
IV	<b>Challenge Phase</b>	Four or five days after reactive food antigens have been removed from diet, the food antigens have cleared but IgG antibody levels remain high. Patient consumes a large amount of the reactive food and experiences exacerbation of symptoms.
V	<b>Elimination Phase</b>	Reactive food is eliminated for 4 to 6 months. IgG levels to the reactive food(s) drop to non- reactive levels.
VI	<b>Reintroduction Phase</b>	After avoiding for 6 months, the reactive food is reintroduced. Patient to consume only modest amounts every fifth day. IgG levels rise when reactive food is consumed but because levels are already low, the elevation in IgG is usually insufficient to induce symptoms. Patient may consume modest amounts of the reactive food once every 5 days. Note that it is not always possible to reintroduce reactive foods into the diet without symptoms reappearing. In some cases, it may be necessary for the patient to permanently avoid the reactive food(s).

June 2025

# Which LifeLabs FST™ Panel Is Right for You?

You've decided to do an IgG food Sensitivity test, now it's time to select a panel that will give you a report of the foods that are most relevant to you and the best value for your money. There are three panel options with Candida included, available to meet your needs:

## LIFELABS FST™ BASIC+

### 101 FOODS:

vegetarian; eggs and dairy;  
meat and seafood

## LIFELABS FST™ VEGETARIAN+

### 165 FOODS:

vegetarian; eggs and dairy.  
Excludes yeast, Aspergillus niger, and  
apricot, as well as the foods listed in  
the fish/seafood and Meat categories

## LIFELABS FST™ ENHANCED+

### 211 FOODS:

vegetarian; eggs and dairy;  
meat and seafood

## WHEN TO SELECT LIFELABS FST™ ENHANCED

Below is a list of the foods that are available only through the LifeLabs FST™ Enhanced+ panel. Using this list, check all foods you consume regularly. If you select four or more foods from the list, the LifeLabs FST™ Enhanced+ panel is the best option of you to ensure you're getting a report of the foods that are most relevant to you and the best value for your money.

### Fish and seafood

- ☐ Anchovy
- ☐ Barnacle
- ☐ Carp
- ☐ Crab
- ☐ Flounder
- ☐ Gilthead bream
- ☐ Haddock
- ☐ Herring
- ☐ Mackerel
- ☐ Monkfish
- ☐ Mussels
- ☐ Octopus
- ☐ Oysters
- ☐ Pike
- ☐ Sardine
- ☐ Scallop
- ☐ Sea bass
- ☐ Shrimp, prawn
- ☐ Squid/cuttlefish
- ☐ Swai fish
- ☐ Trout
- ☐ Turbut
- ☐ Zander

### Fruit

- ☐ Avocado
- ☐ Blackberry
- ☐ Blueberry
- ☐ Cranberry
- ☐ Currant
- ☐ Date
- ☐ Fig
- ☐ Grapefruit
- ☐ Guava
- ☐ Lime
- ☐ Lychee
- ☐ Mandarin
- ☐ Mango
- ☐ Mulberry
- ☐ Papaya
- ☐ Peach
- ☐ Pear
- ☐ Plum
- ☐ Pomegranate
- ☐ Rhubarb

### Vegetables

- ☐ Artichoke
- ☐ Arugula
- ☐ Asparagus
- ☐ Bok Choi
- ☐ Brussels sprouts
- ☐ Cauliflower
- ☐ Celery
- ☐ Chard
- ☐ Endive
- ☐ Fennel
- ☐ Iceberg lettuce
- ☐ Parsnip
- ☐ Pumpkin
- ☐ Radish
- ☐ Savoy cabbage
- ☐ Spinach
- ☐ Sweet potato
- ☐ White cabbage

### Dairy/Eggs

- ☐ Quail egg
- ☐ Ricotta

### Herbs/Spices

- ☐ Bay leaf
- ☐ Black cumin
- ☐ Capers
- ☐ Caraway
- ☐ Cardamom
- ☐ Chive
- ☐ Clove
- ☐ Coriander
- ☐ Cumin
- ☐ Garden cress
- ☐ Ginger
- ☐ Marjoram
- ☐ Saffron
- ☐ Sage

### Mushroom

- ☐ Chanterelle
- ☐ Porcini mushroom
- ☐ Shiitake

### Nuts/Seeds

- ☐ Brazil nut
- ☐ Broad bean
- ☐ Chia seeds
- ☐ Chickpeas
- ☐ Coconut
- ☐ Kidney bean
- ☐ Lentil
- ☐ Macadamia nut
- ☐ Mung bean
- ☐ Pine nut
- ☐ Sweet chestnut
- ☐ White beans

### Gluten free grains

- ☐ Amaranth
- ☐ Cassava
- ☐ Lupini bean
- ☐ Teff

### Meat

- ☐ Duck
- ☐ Goat
- ☐ Goose
- ☐ Ostrich meat
- ☐ Rabbit/hare
- ☐ Venison
- ☐ Veal
- ☐ Wild boar

### Miscellaneous

- ☐ Camomile
- ☐ Carob bean
- ☐ Ginkgo biloba
- ☐ Green tea
- ☐ Nori
- ☐ Wakame

# Food Reintroduction Symptoms Tracker

- Remove the foods that are reactive, following your Healthcare Provider’s guidance and advice.
- Track your symptoms, and if they have improved, you may want to test yourself for reactions by slowly reintroducing foods into your diet. Consult with your Healthcare Provider before doing this.
- Choose one test food to reintroduce into your diet at a time.
- Using the tracker below, take detailed notes on how you feel, and make a point to notice everything you’re feeling.

	Day 1	Day 2	Day 3	Day 4	Day 5
Time					
Food					
Digestion/ Bowel Function					
Joint/Muscle Aches					
Headache/ Pressure					
Nasal or Chest Congestion					
Kidney/ Bladder Function
